## (1) Stability and Antibiofilm Efficiency of Slightly Acidic Electrolyzed Water Against Mixed-Species of *Listeria monocytogenes* and *Staphylococcus aureus*

In the natural environment, most microorganisms live in mixed-species biofilms, in which the metabolism and growth of organisms are different from that in single-species biofilms. Adhesive bacteria and their biofilms on the surface of food processing equipment are the sources of cross-contamination, leading to the risk for humans. Slightly acidic electrolyzed water (SAEW) has been proposed as a novel sanitizer in the food and agriculture industry. In this study, we investigated the changes in the physical properties of SAEW under different conditions and the disinfection abilities of SAEW against spore-forming and non-spore-forming pathogens. Furthermore, we examined the disinfection abilities of SAEW after 12 months of shelf life on a mixed-species biofilm of *Listeria monocytogenes* Scott A and *Staphylococcus aureus*. The results showed that SAEW at 30 and 50 ppm achieved all-kill of the spore-forming pathogen *Bacillus cereus* within 30 s. Changes in the ACC and pH of the produced SAEW were generally affected by the storage conditions. Both spore-forming and non-spore-forming pathogens were not detected under treatment with 50 ppm SAEW for 5 min under HDPE-closed conditions throughout the whole storage period. Moreover, 25 mg/L SAEW can inactivate *L. monocytogenes* Scott A and *S. aureus* biofilm cells in ~2.45 and 2.57 log CFU/mL in biofilms within 5-min treatment. However, the decline of the two bacteria in the mixed-species biofilm was 1.95 and 1.43 log CFU/mL, respectively. The changes in the cell membrane permeability of the mixed-species biofilm under treatment with SAEW were observed by using atomic force microscopy and confocal laser scanning microscopy. *L. monocytogenes* Scott A was more sensitive to SAEW in the mixed-species biofilm cells. These findings exhibited strong antibiofilm activities of SAEW in impairing biofilm cell membranes, decreasing cell density, and eliminating biofilm, which suggest that SAEW is an excellent antibacterial agent in the food processing industries.

SAEW and Mixed-Species Biofilm

GRAPHICAL ABSTRACT |

### CONCLUSION

To our knowledge, this is the first study to assess the effects of SAEW on the mixed-species biofilms of *S. aureus* and *L. monocytogenes* Scott A during a shelf life of 12 months.

The changes in physical properties and antimicrobial activity of SAEW are highly dependent on the storage time and conditions, including the material and open-closed environment. Neither spore-forming nor non-spore-forming pathogens were detectable for a 5-min reaction throughout the whole storage period under HDPE-closed conditions of 50 ppm SAEW.

**ABSTRACT** Hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) and hypochlorous acid (HOCl) are biocides used for cleaning and debriding chronic wound infections, which often harbor drug resistant bacteria. Here, we evaluated the in vitro activity of H<sub>2</sub>O<sub>2</sub> and HOCl against 27 isolates of eight bacterial species involved in wound infections. Minimum inhibitory concentrations (MICs) and minimum biofilm bactericidal concentrations (MBBCs) were measured. Compared to their respective MICs, MBBCs of isolates exposed to H<sub>2</sub>O<sub>2</sub> were 16- to 1,024-fold higher, and those exposed to HOCl were 2- to 4-fold higher. These results suggest that HOCl has similar activity against planktonic and biofilm bacteria whereas the activity of H<sub>2</sub>O<sub>2</sub> is less against biofilm than planktonic bacteria.

**TABLE 1** Susceptibility of bacterial isolates (planktonic and biofilm forms) to H<sub>2</sub>O<sub>2</sub> and HOCl

<sup>a</sup>Susceptibility data values (i.e., MIC, MBIC, and MBBC) are represented as means ± SD (n=3). All experiments were performed in triplicates. *S. aureus* USA100, USA200, and USA300 strains were provided by Henry Chambers III (University of California, San Francisco). Xen 30, Xen 43, and Xen 5 strains were provided by Caliper Life Sciences. *P. aeruginosa* PAO1, PA14, and PA14 Δ*katAB* strains were provided by Daniel Hassett (University of Cincinnati). *A. baumannii* ARLG-1268 was provided by the Antibacterial Resistance Leadership Group of the National Institutes of Health.

It is our view that to ideally use H<sub>2</sub>O<sub>2</sub> as an antibiofilm agent, a high working concentration of H<sub>2</sub>O<sub>2</sub> along with a long surface contact time are likely to be needed.

The mean MICs of HOCl against the bacteria studied ranged from 0.50 to 1.99 mM. In contrast to H<sub>2</sub>O<sub>2</sub>, we did not observe large variations in MIC, MBIC, or MBBC ranges. The mechanism of action of HOCl is incompletely defined, and how bacterial molecular stress mechanisms respond to it are also poorly understood. It has been proposed that the transport of free chlorine into biofilms is a significant factor in imparting resistance (35). In work done by Castillo et al., HOCl was used as oral rinses to remove dental plaque (36). HOCl was a more effective antibacterial agent than chlorhexidine and reduced bacterial viability of different periodontopathic bacteria found in biofilms. The authors suggested that HOCl can oxidize taurine, an amino acid, promoting the formation of chlorine-aurine complexes that have antibacterial activity. In another study, 0.018% HOCl (2.72 mM) removed lipopolysaccharides found in *Porphyromonas gingivatis* biofilms. The authors suggested that HOCl forms chlorohydrins, which attack acyl chains in unsaturated fatty acids, causing cell membrane damage along with cytolysis (37). HOCl has been found to interact with sulfur-containing amino acids, aromatic amino acids, nitrogen-containing compounds, and lipids (38). Various ATP-independent HOCl-sensing chaperones, like Hsp33, RidA, CnoX, etc., have been found to be activated as part of the immediate counter-response to HOCl, especially in Gram-negative bacteria.

In conclusion, our data suggest that HOCl has similar activity against planktonic and biofilm bacteria, whereas H<sub>2</sub>O<sub>2</sub> is substantially less active against biofilm than planktonic bacteria. We did not observe the emergence of antibiofilm resistance with repeated exposure to either H<sub>2</sub>O<sub>2</sub>- or HOCl-producing e-scaffolds under the conditions studied.

#### Abstract

**Background:** Caries and periodontitis are amongst the most prevalent diseases worldwide, leading to pain and loss of oral function for those affected. Prevention relies heavily on mechanical removal of dental plaque biofilms but for populations where this is not achievable, alternative plaque control methods are required. With concerns over undesirable side-effects and potential bacterial resistance due to the use of chlorhexidine gluconate (CHX), new antimicrobial substances for oral use are greatly needed. Here we have investigated the antimicrobial effect of hypochlorous acid (HOCl), stabilized with acetic acid (HAc), on oral biofilms and compared it to that of CHX. Possible adverse effects of stabilized HOCl on hydroxyapatite surfaces were also examined.

**Methods:** Single- and mixed-species biofilms of six common oral bacteria (*Streptococcus mutans*, *Streptococcus gordonii*, *Actinomyces odontolyticus*, *Veillonella parvula*, *Parvimonas micra* and *Porphyromonas gingivalis*) within a flow-cell model were exposed to HOCl stabilized with 0.14% or 2% HAc, pH 4.6, as well as HOCl or HAc alone. Biofilm viability was assessed in situ using confocal laser scanning microscopy following LIVE/DEAD® BacLight™ staining. In-situ quartz crystal microbalance with dissipation (QCM-D) was used to study erosion of hydroxyapatite (HA) surfaces by stabilized HOCl.

**Results:** Low concentrations of HOCl (5 ppm), stabilized with 0.14% or 2% HAc, significantly reduced viability in multi-species biofilms representing supra- and sub-gingival oral communities, after 5 min, without causing erosion of HA surfaces. No equivalent antimicrobial effect was for CHX. Gram-positive and Gram-negative bacteria showed no significant differential susceptibility to stabilized HOCl.

**Conclusions:**

At low concentrations and with exposure times which could be achieved through oral rinsing, HOCl stabilized with HAc had a robust antimicrobial activity on oral biofilms, without causing erosion of HA surfaces or affecting viability of oral keratinocytes. This substance thus appears to offer potential for prevention and/or treatment of oral biofilm-mediated diseases.

**Keywords:** Biofilm control, Oral disease, Caries, Periodontitis, Oral infection

In summary, this study shows that at low concentrations and with short exposure times, HOCl stabilized with HAc has a robust antimicrobial activity against biofilms of a range of different oral bacteria, without causing erosion of HA surfaces or affecting keratinocyte viability. In the light of concerns regarding development of resistance to antibiotics and even CHX, this substance appears to offer potential for the prevention and treatment of oral biofilm-mediated diseases. Further studies are now required to investigate the efficacy of stabilized HOCl in vivo, where factors such as substantivity and the role of saliva can be assessed.

**Hypochlorous acid has emerged as a potential alternative to conventional antibiotics due to its broad-spectrum antimicrobial activity**

**Maheer M Aki\***

**Int J Clin Microbiol Biochem Technol. 2023; 6: 001-004.**

Hypochlorous acid can penetrate the extracellular matrix of biofilms and kill bacteria by the same mechanisms as it does for planktonic bacteria.
